# Linear Programming II

David Woodruff

#### Outline

- Another linear programming example l1 regression
- Seidel's 2-dimensional linear programming algorithm
- Ellipsoid algorithm, and continued discussion of simplex algorithm

### L1 Regression

- Input: n x d matrix A with n larger than d, and n x 1 vector b
- Find x with Ax = b
- Unlikely an x exists, so instead compute  $\min_x \sum_{i=1,\dots,n} |\, A_i \cdot x \, b_i|$
- Solve with linear programming? How to handle the absolute values?
- Create variables  $s_i$  for i = 1, ..., n with  $s_i \ge 0$ 
  - Also have variables  $x_1, ..., x_d$
- Add constraints  $A_i \cdot x b_i \le s_i$  and  $-(A_i \cdot x b_i) \le s_i$  for i = 1, ..., n
- What should the objective function be?
- min  $\sum_{i=1,...,n} s_i$

# Simple Linear Regression

absorb this by tex)

- Goal: given  $(y_i, x_i)$ , i = 1, ..., n, estimate  $\beta_0, \beta_1$
- $\varepsilon_i$  is the error term; can always assume  $E(\varepsilon) = 0$ .
- Minimize errors how do we define that?
- One criterion is least squares:

$$\min_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\min_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

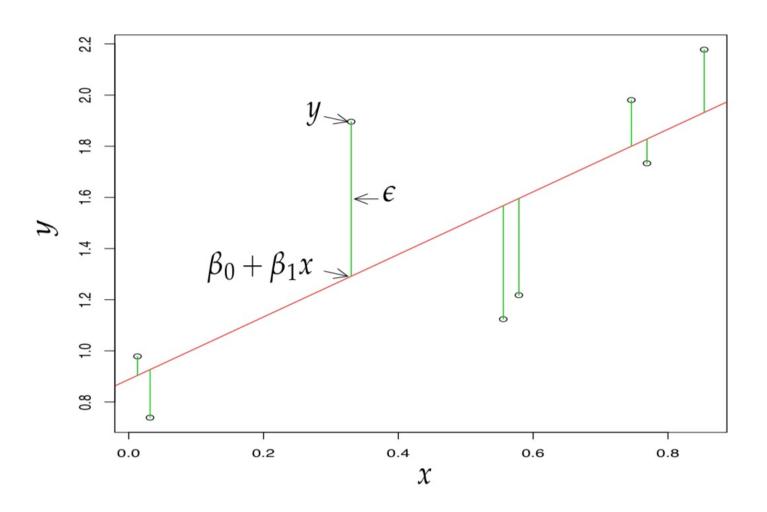

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n \varepsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

$$\max_{\beta_0,\beta_1} \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

# Least Squares Estimate

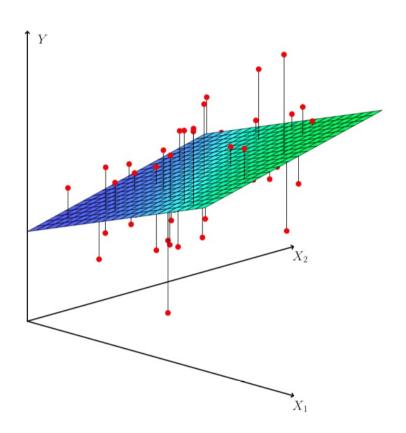

#### Matrix Notation

Let

## Least Squares Estimate

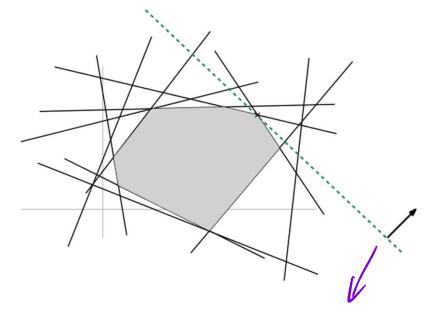

We estimate the parameters using least squares, i.e.

$$\arg\min_{\beta_0,\beta_1,...,\beta_p} \frac{1}{n} \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_{i1} - \dots - \beta_p x_{ip})^2$$

# Seidel's 2-Dimensional Algorithm

- Variables  $x_1, x_2$
- Constraints  $a_1 \cdot x \le b_1, ..., a_m \cdot x \le b_m$
- Maximize c · x
- Start by making sure the program has bounded objective function value

#### What if the LP is unbounded?

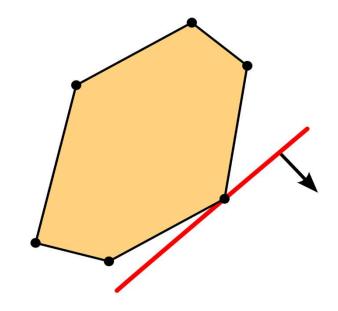

- Add constraints  $-M \le x_1 \le M$  and  $-M \le x_2 \le M$  for a large value M
- How large should M be?
- Maximum, if it were bounded, occurs at the intersection of two constraints  $ax_1+bx_2=c$  and  $ex_1+fx_2=d$

$$\begin{bmatrix} a & b & x_1 \\ e & f & x_2 \end{bmatrix} = \begin{bmatrix} c \\ d \end{bmatrix}$$

- If a, b, e, f, c, d are specified with L bits, can show  $|x_1|$ ,  $|x_2|$  specified with O(L) bits
- Can evaluate the objective function on each of the 4 corners of the box to find two constraints  $c_1$ ,  $c_2$  which give the maximum

# What Convexity Tells Us

 Maximizing a linear function over the feasible region finds a tangent point

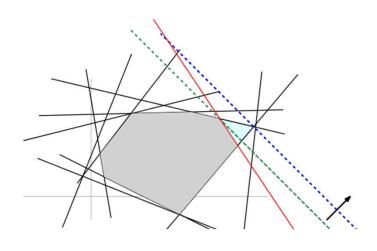

- What's a super naïve  $O(m^3)$  time algorithm?
- Find the intersection of each pair of constraints, compute its objective function value, and make sure this point is feasible for all constraints
- What's a less naïve  $O(m^2)$  time algorithm?

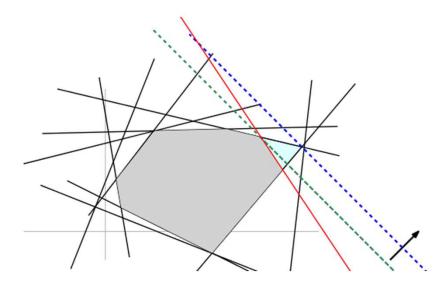

# An $O(m^2)$ Time Algorithm

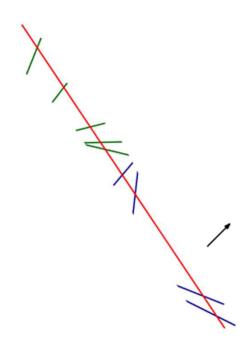

- Order the constraints  $a_1 \cdot x \leq b_1, ..., a_m \cdot x \leq b_m, c_1, c_2$
- Recursively find optimum point  $x^*$  of  $a_2 \cdot x \le b_2, ..., a_m \cdot x \le b_m, c_1, c_2$
- If  $a_1x^* \le b_1$ , then  $x^*$  is overall optimum
- Otherwise, new optimum intersects the line  $a_1x^* = b_1$
- Need to solve a 1-dimensional problem

#### 1-Dimensional Problem

- Takes O(m) time to solve
- Note: new optimum might not be determined by one of the two constraints determining the old optimum

# An $O(m^2)$ Time Algorithm

- Recursively find optimum point  $x^*$  of  $a_2 \cdot x \le b_2, ..., a_m \cdot x \le b_m, c_1, c_2$
- If  $a_1x^* \le b_1$ , then  $x^*$  is still optimal
- Otherwise, new optimum intersects the line  $a_1 \cdot x = b_1$
- Solve a 1-dimensional problem in O(m) time
- $T(m) = T(m-1) + O(m) = O(m^2)$  time
- Can we get O(m) time?

1. Soft 
$$O(m \log m)$$

2. Vecuraive strat from  $A_1 \times \subseteq b_2$   $T(m-1)$ 

3.  $A_2 \times \subseteq b_3$   $X' \times \subseteq b_4$   $X' \times \subseteq b_5$   $T(m-1)$ 

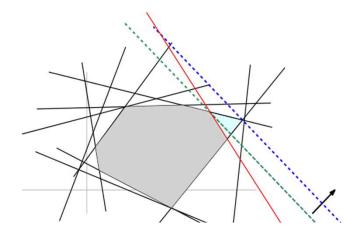

3.  $A_2 \times \subseteq b_4$   $X' \times \subseteq b_5$   $X' \times \subseteq b_6$   $X' \times \subseteq b_7$   $Y \times \subseteq b$ 

# Seidel's O(m) Time Algorithm

- Order constraints randomly:  $a_{i_1} \cdot x \le b_{i_1}, ..., a_{i_m} \cdot x \le b_{i_m}, c_1, c_2$ 
  - Leave  $c_1$ ,  $c_2$  at the end
- Recursively find the optimum  $x^*$  of  $a_{i_2}\cdot x \leq b_{i_2}$  , ... ,  $a_{i_m}\cdot x \, \leq b_{i_m}$  ,  $c_1$  ,  $c_2$
- Case 1: If  $a_{i_1} \cdot x^* \le b_{i_1}$ , then  $x^*$  is overall optimum
  - O(1) time
- Case 2: If  $a_{i_1} \cdot x^* > b_{i_1}$ , then we need to intersect the line  $a_{i_1} \cdot x = b_{i_1}$  with each other line  $a_{i_1} \cdot x = b_{i_1}$  and solve a 1-dimensional problem in O(m) time

# Backwards Analysis

- Let  $x^*$  be the optimum point of  $a_{i_2} \cdot x \le b_{i_2}$ , ...,  $a_{i_m} \cdot x \le b_{i_m}$ ,  $c_1$ ,  $c_2$
- What is the chance that  $a_{i_1} \cdot x^* > b_{i_1}$ ?
- Suppose the optimum x' of  $a_{i_1} \cdot x \leq b_{i_1}, \dots, a_{i_m} \cdot x \leq b_{i_m}, c_1, c_2$  is the intersection of two constraints  $a_{i_j} \cdot x = b_{i_j}$  and  $a_{i_j} \cdot x = b_{i_j}$ ,
- If we've seen these two constraints, then the new constraint  $a_{i_1} \cdot x \leq b_{i_1}$  can't change the optimum. Otherwise, optimum would change
- Expected time for processing the last constraint is at most  $(1-2/m) \cdot O(1) + (2/m) \cdot O(m) = O(1)$

# Backwards Analysis

• We process the randomly ordered constraints in reverse order:

$$a_{i_1} \cdot x \le b_{i_1}, ..., a_{i_m} \cdot x \le b_{i_m}, c_1, c_2$$

When processing the last constraint of:

$$a_{i_j} \cdot x \le b_{i_j}, ..., a_{i_m} \cdot x \le b_{i_m}, c_1, c_2$$

the expected amount of time is

$$(1-2/(m-j+1)) \cdot O(1) + (2/(m-j+1)) \cdot O(m-j+1) = O(1)$$

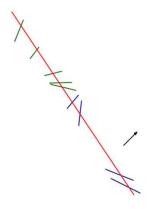

- The expected total time to process m constraints is  $\sum_j O(1) = O(m)$ , as desired!
- Formally, let T(m) be the expected time to process all m constraints

$$T(m) \le (1-2/m) O(1) + (2/m) \cdot O(m) + T(m-1)$$
  
=  $O(1) + T(m-1)$ 

= O(m). Also add initial constant time for finding  $c_1$ ,  $c_2$ 

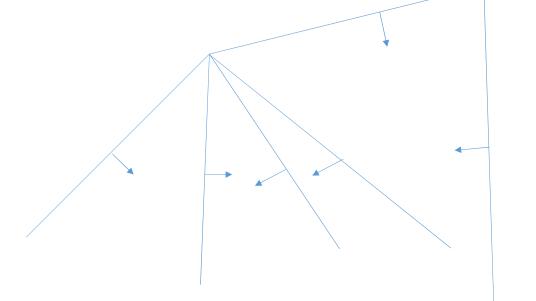

#### What if the LP is Infeasible?

- Let j be the largest index for which  $a_{i_j} \cdot x \leq b_{i_j}, \dots, a_{i_m} \cdot x \leq b_{i_m}, c_1, c_2$  is infeasible. That is,  $a_{i_{j+1}} \cdot x \leq b_{i_{j+1}}, \dots, a_{i_m} \cdot x \leq b_{i_m}, c_1, c_2$  is feasible
- Since  $a_{i_{j+1}} \cdot x \le b_{i_{j+1}}, \dots, a_{i_m} \cdot x \le b_{i_m}, c_1, c_2$  is randomly ordered, we spend an expected O(m) time to process such constraints
- When processing  $a_{i_j} \cdot x \le b_{i_j}$  we will find the constraints are infeasible in O(m) time when solving the 1-dimensional problem

#### What If More than 2 lines Intersect at a Point?

• 2 of the constraints "hold down" the optimum

Additional constraints can only help you

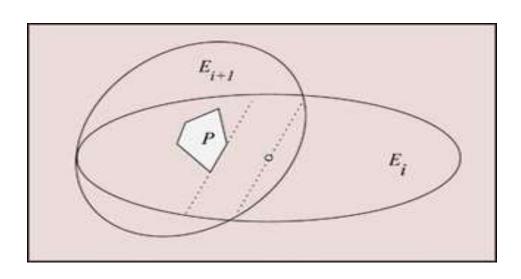

# Higher Dimensions?

- The probability that our optimum changes is now at most d/m instead of 2/m
- When we find a violated constraint, we need to find a new optimum
- New optimum inside this hyperplane
  - Project each constraint into this hyperplane
  - Solve a (d-1)-dimensional linear program on m-1 constraints to find optimum
  - Time is d<sup>O(d)</sup>m

# Ellipsoid Algorithm

Solves feasibility problem

Replace objective function with constraint, do binary search Replace "minimize  $x_1 + x_2$ " with  $x_1 + x_2 \le \lambda$ 

Can handle exponential number of constraints if there's a separation oracle

# Karmarkar's Algorithm

- Works with feasible points but doesn't go corner to corner
- Moves in interior of the feasible region "interior point method"
